1   INTRODUCTION:

1.1   BACKGROUND / JUSTIFICATIONS TO THE STUDY

The rapid rise of Non-communicable diseases (NCDs) represents one of the major health challenges to global development. Non-communicable Diseases (NCDs) were estimated to have contributed to almost 60% of deaths in the world and 43% of the global burden of disease in 1999. Based on current trends, by the year 2020 these diseases are predicted to account for 73% of deaths and 60% of the disease burden. It is further estimated that by 2020 over 70% of the global burden of disease will be caused by NCDs (especially cancer, diabetes, cardiovascular diseases and chronic respiratory diseases), mental health disorders and injuries.

NCDs, are already of major importance in developed countries and are rapidly becoming a major public health threat in the developing world. According to a recent WHO NCD Surveillance Strategy report, over a period of 30 years the burden of disease from NCDs for developing and newly industrialized countries is expected to rise by more than 60% by 2020, compared to a rise of less than 10% in developed countries

(http://www.who.int/entity/ncd_surveillance/strategy/en/).(http://www.who.int/entity/ncd_surveillance/strategy/en/).

NCDs particularly cardiovascular diseases, diabetes, cancer, chronic obstructive pulmonary diseases and injuries, are increasing in epidemic proportions in the African region. According to the World Health Report 2001, NCDs accounted for 22% of the total deaths in Africa.   Cardiovascular diseases alone were responsible for 9.2% of the deaths, killing even more people than malaria did. Hypertension prevalence for example, ranges from 10% to 40% in urban areas of some African countries; mortality and disability due to stroke, which is mainly

caused by hypertension, is higher in most countries of the region than in industrialized countries. Rheumatic fever/rheumatic heart disease is still the main cause of acquired cardiovascular disease in children and young adults in Africa. Eritrea is no exception.

1.2 ERITREAN HEALTH SITUATION

1.2.1. CHANGING BURDEN OF DISEASE

Eritrea is already experiencing something of a shift in the pattern of diseases. The efforts made in the control of communicable diseases and the changes in the living standards and lifestyles of Eritrean people as well as environmental factors are leading to an epidemiological shift from communicable to non-communicable diseases

Already there has been some improvement in some key health status and health service indicators in Eritrea compared to rest of sub-Saharan Africa. All these are indicative of improvement in the control of communicable diseases. It is thus expected that non-communicable diseases will become increasingly important as a cause of morbidity and mortality. The status of the indicators is shown in Table 1.

Table 1.1: Some key health status and health service indicators in Eritrea

Indicator	1995 EDHS	2002 EDHS	Sub-Saharan Africa
Infant mortality/1000	72	47.7	94
Under five mortality/1000	136	93.3	151
MMR/100000	998		1100
Life expectancy at birth		51	45.4

Though the disease burden in Eritrea, as in many other developing countries is still dominated by communicable diseases, non-communicable diseases are rapidly becoming an important cause of morbidity and mortality. Although, ARI,

diarrhoea and other communicable diseases were the major causes of outpatient and inpatient morbidity and mortality, their percentage occurrence remained consistent or decreased compared to other causes of morbidity. The situation indicates that the combined effort or interventions of the Ministry and other partners in controlling the occurrence of these diseases is already having an impact. The most recent report of Health Services Activity from Health Management Information System for 2003 bears this out.

Among the ten leading causes of outpatient morbidity in hospitals and health centres in 2002, in those under five years, oro-dental infection and disorder plus bronchitis/emphysema (COPD) combined (2.4%)were 7th above malaria (2.1%). Over the same period, in those five years and above, non-communicable diseases namely, gastritis/DU, oro-dental infection and disorders plus rheumatoid arthritis combined (12.8%) were the second overall cause of outpatient morbidity in hospitals and health centers surpassed only by ARIs (21.1%).

Again during 2002, among the ten leading causes of admissions in hospitals and health centers; in those under five years, two non-communicable disorders, cataracts and other lens disorders combined with asthma (1.7%) ranked 7th above TB and HIV/AIDS. In those over 5 years, non-communicable diseases namely, cataracts and other lens disorders plus gastritis/duodenal ulcer plus hypertension (6.8%) ranked 4th after malaria, abortion and ARI.

Among the ten leading causes of deaths in hospitals and health centers in 2003; In those over 5 years, hypertension, heart failure, diabetes mellitus and liver diseases combined (35.5%) were by far the leading causes of deaths in hospitals and health centers. In addition, hypertension, heart failure and diabetes mellitus were each ranked above malaria as a cause of death. The distribution is shown in Table 2.

Table 1.2: Ten leading causes of deaths in hospitals and health centers in 2003

Rank	Under five years	Deaths		Five years and above	Deaths	
		No	%		No	%
1	ARI	199	33.6	HIV/AIDS	182	18.4
2	Anaemia and malnutrition	133	22.5	TB	137	13.8
3	Diarrhoea all forms	122	20.6	ARI	127	12.8
4	Septicaemia	74	12.5	Hypertension	101	10.2
5	Malaria all types	29	4.9	Heart Diseases	100	10.1
6	HIV/AIDS	22	3.7	Other liver diseases	90	9.1
7	Heart failure	4	0.7	Anaemia malnutrition	88	8.9
8	TB all types	3	0.5	Diabetes mellitus	69	6.8
9	Urinary tract infections	3	0.5	Malaria all types	50	5.1
10	Skin infections and scabies	3	0.5	Septicaemia	48	3.5

1.2.2. TRENDS OF THE LEADING CAUSES OF MORBIDITY AND MORTALITY

No significant changes were observed in the ranks of the leading causes of morbidity and mortality in the last five years. It is however interesting to note that malaria that was previously 1st or 2nd cause of outpatient morbidity was 7th and 8th in 2002. Furthermore, malaria was not one of the ten causes of mortality in the age group five years and above unlike in the previous five years when it was ranked from the first to the sixth cause of death.

Of special interest is the fact that hypertension, diabetes mellitus and liver diseases are among the leading ten diseases. Also note must be taken of the

fact that gastritis and duodenal ulcer (probably related to psycho-social and postwar traumatic stress syndrome problems) has been the 4th leading cause of outpatient morbidity in those aged five years and above since 2000 while it was ranked 6th in the year 1998.

Within the backdrop of this situation, and in order to implement a National Program of Non-communicable disease risk factor surveillance, prevention and control in Eritrea, a Non-Communicable Diseases (NCDs) unit has recently been established in the newly created Disease Prevention and Control (DPC) division of the Ministry of Health. Its main mandate is get the programme running as soon as possible.

The purpose of this survey is to produce baseline data that will reveal the actual picture of NCD risk factors in Eritrea, shape the planning of the intervention programme and be used to evaluate process and output indicators during the implementation of the national NCD programme.

1.3   ERITREA COUNTRY PROFILE:

1.3.1. GENERAL INFORMATION

Eritrea is situated in the Horn of Africa and has an area of 122,000 square kilometres. To the east the country is bordered by the Red Sea. Djibouti borders the country to the southeast, Ethiopia in the south, and the Sudan in the north and west. Administratively the country is divided into six Zobas or regions.

Eritrea is a land of contrasts with land rising from below sea level to 3,000 meters above sea level. There are three major physiographic zones: the Western Lowlands, the Central and Northern Highlands, and the Eastern Lowlands.

Rainfall in Eritrea ranges from less than 200 mm per annum in the eastern lowlands to about 1,000 mm per annum in a small pocket of the Escarpment; the annual rainfall in the highlands ranges from 450 mm – 6000 mm. The southern part of the western lowlands receives 600 – 800 mm of rain per annum, but

rainfall decreases substantially as one move northward. The extremely low rainfall in the eastern lowlands causes aridity and a hostile environment for agriculture, grazing and industry. There are two major periods of precipitation in Eritrea. One, from June to September, covers both the western lowlands and highlands. The second comes between October and March and covers the eastern lowlands.

1.3.2. HISTORY

Because of Eritrea's strategic position on the Red Sea, it has fallen victim to many invaders and colonizers. More recently the country was engaged in three decades of struggle for self-determination from Ethiopia, which culminated in formal independence in 1993.

1.3.3. ECONOMY

Agriculture and pastoralism are the main sources of livelihood for about 80% of Eritrea's population. The agricultural sector depends mainly on rain, with less than 10% of the arable land currently irrigated. Consequently, productivity is low and the agricultural sector, including livestock and fisheries, accounts for only one-fifth of the

Gross domestic product (GDP). Eritrea is one of the poorest countries in the world with a GDP per capita of about US$ 200, well below the average of US$ 270 for less developed countries (UNDP, 2001).

1.3.4. POPULATION

No population census has ever been carried out in Eritrea. As a result, there are no reliable estimates of the population currently residing in Eritrea or the population of Eritreans living abroad, many of whom are potential returnees.

However, based on a population count, the Ministry of Local Government estimated the total population of Eritrea to be about 3.2 million in 2001.

1.3.5. HEALTH SERVICES AND PROGRAMMES

The introduction of modern health services into Eritrea is relatively recent. Italians established the first hospital in Asmara at the end of the nineteenth century. In the period prior to federation with Ethiopia, Eritrea had a relatively advanced health care system at least by the standards of the time. However, three decades of the war for independence, almost all existing health facilities were destroyed, medical supplies were disrupted and health professionals abandoned their posts.

Since independence, the Ministry of Health (MoH) has made significant progress in ensuring access to health care services through restoration of health facilities damaged during the war, the provision of adequate supplies of drugs and equipment, the expansion of available health services to communities where they are lacking, through construction of new facilities and the training of qualified health personnel.

2.0   OBJECTIVE

2.1   GOAL

The overall goal is to set up a national surveillance system for the major non-communicable diseases (NCD) and their risk factors by using a combination of the WHO STEPwise approach and routine data collection in order to provide information for planning a national NCD prevention and control programme.

2.2   SPECIFIC OBJECTIVES:

1. To conduct a baseline survey of the main risk factors for the major NCDs in the urban and rural areas of the 6 Zoba of the country
2. To develop capacity of MOH staff at different levels for NCDs risk factor surveillance
3. To set up a national programme for early detection, prevention and control of NCDs and their risk factors
4. To set up a Community-based surveillance system for NCDs and their risk factors.
5. To develop appropriate IEC materials for early detection, prevention and control of NCDs and their risk factors

2.3   EXPECTED OUTCOMES

1. A baseline survey of the main risk factors for the major NCDs is carried out in the urban and rural areas of the 6 Zoba of the country and its results used to influence government policy.

2. MOH personnel at different levels are able to carry out NCD risk factor surveillance activities within the communities of Eritrea

3. An operational national NCD programme is set up with major arms of prevention (health promotion and health protection) and control (production of management guidelines and capacity building)
4. A Community-based surveillance programme for NCDs is setup (surveillance guidelines produced and training assured)
5. Appropriate IEC materials for early detection, prevention and control of NCDs developed based on the evidence obtained from the baseline survey.

3.0   METHODOLOGY

3.1.   INTRODUCTION

The study was carried out amongst all the nine ethnic groups in Eritrea. It was a cross sectional baseline survey of the principal risk factors of the major NCDs in Eritrea that ran from the August to November 2004. The WHO STEPwise approach for surveillance of NCD risk factors was used.

The STEPwise approach provides a framework for surveillance of NCD risk factors, NCD-specific morbidity and mortality. The STEPs approach is based on the concept that surveillance systems require standardized data collection to ensure comparability over time and across locations. It is also sufficiently flexible to be appropriately adaptable in a variety of country situations and settings.

A 'risk factors' (in this context) refer to any attribute, characteristic, or exposure of an individual, which increases the likelihood of developing a non-communicable disease. Within a community, measurements of these risk factors are used to describe the distribution of future disease in a population. Because many factors associated with disease cannot be modified, emphasis in any surveillance system should be given to those risk factors that are amenable to intervention (modifiable). It has been shown that surveillance of just eight selected risk factors, which reflect a large part of future NCD burden, can provide a measure of the success of interventions.

The eight risk factors include the following:
1. Tobacco use,
2. Alcohol consumption,
3. Physical inactivity,
4. Nutrition
5. Obesity
6. Raised blood pressure.

7. Blood glucose
8. Blood lipids

STEPS is a sequential process starting with gathering information on key risk factors by the use of questionnaires (Step 1), then moving to simple physical measurements (Step 2), and only then recommending the collection of blood samples for biochemical assessment (Step 3).

In this study, Steps 1 and 2 were used. Information was thus collected on Tobacco use, Alcohol consumption, physical inactivity, nutrition, obesity and raised blood pressure.

3.2. STUDY DESIGN AND SAMPLE SIZE

A sample size of 2304 subjects (N) in the 6 zones was calculated using the formula:

N= Z^2pq divided by E^2

Where Z is the Z score

P is the proportion of the factor under investigation

q=1- p

E is the maximum error allowed.

A two stage stratified cluster sampling procedure with Primary sampling unit (PSU) = clusster selected from all six zones was used. The PSU (cluster) was selected with Probability Proportional to Size of the village (PPS) in terms of households. A cluster could correspond to a village or cut across villages. In some instances, a village could contain more than one cluster.

One hundred and twenty three clusters were selected from the 6 zones and 20 individuals (subjects) aged 15-64 years old were targeted from each cluster for interview. A total of 20 x 123 (2 460) were thus targeted. (NB. WHO recommends a minimum of 400 subjects per age group i.e. 200 male and 200 female, thus, 2000 for the five 10-year age groups).

Systematic sampling of households was done using the given sampling interval for that village (see annex). The first household was selected by spinning a bottle at the middle of every village and all eligible subjects per household (15-64 years) were enlisted and one randomly selected per age group.   Each time a subject was selected for interview and physical examination, that individual was crossed out from the age group checklist till the total sample size was attained.

Table 3.1 Cluster Allocation per Zoba

Zoba	No. of Clusters
Anseba	20
Debub	31
Gash-Barka	24
Maekel	24
NRS	18
SRS	6
Total	123

At the second stage, **20 individuals** between the ages 15-64 from each cluster were interviewed. Due to logistic impracticability of obtaining a list of households in each cluster, systematic random sample could not be applied. The households were thus selected using simple random technique.

The individuals to be interviewed were clustered into Age groups of 10 years. This means that, in each age group, 2 males and 2 females were selected.

The list of all persons 15 to 64 years was obtained from the head of the household or his representative. The persons were allocated numbers and one person randomly selected.

In the absence of an eligible candidate in the household, it was dropped and the next household selected and a new sapling interval started thereafter.

3.3 DATA COLLECTION PROCEDURE:

3.3.1. TRAINING:

The data collectors were given a 2-day training that included interview techniques, introduction to NCDs and detailed introduction to the data collection instruments and physical measurement instruments.

There were practical sessions to practice with the questionnaire and the physical measurement equipment. The training took place between the 4th and 5th of September 2004 and data collection followed suit between the 6th and the 13th of September 2004.

Field guidelines were likewise developed and given to each team.

3.3.2 THE QUESTIONNAIRE

The questionnaire was developed from the Steps standard questionnaire and adapted for Eritrea. The questionnaire was pre-tested at the Orotta School of medicine and modified according to pre-testing findings. It was also translated into the local Tigrinya language.

Some of the terms standardized include:

Standard drink: 1 standard drink equals to 1 bottle of beer (285 ml) or 1 measure of spirits (30ml) or 1 glass of wine (120 ml) or 1 measure of aperitif (60 ml) or 2 measures of Sewa. For those who take a mixture of different types of drinks, collate all and then calculate the number of standard drinks.

Serving of fruit: 1 serving of fruit = 1 medium size of apple, banana, orange or ½ cup of chopped, cooked or canned fruit or ½ cup of fruit juice.

***Serving of Vegetable**: 1 serving of vegetable = 1 cup of raw vegetables (spinach, salad), ½ cup of cooked or chopped vegetables (tomato, carrot, pumpkin, corn, Chinese cabbage, fresh beans) or ½ cup of vegetable juice.*

***Moderate physical activity**: Involve moderate physical effort, makes you breath somewhat harder than normal. Examples are cleaning, farming, painting, gardening, swimming, and climbing stairs.*

***Vigorous physical activity**: Involve hard physical effort, makes you breath much harder than normal. Examples are carrying heavy load, heavy construction, digging, and shoveling, sawing wood, running, strenuous sports.*

3.3.3. PHYSICAL MEASUREMENTS:

The physical measurements taken were Blood pressure, Height, Weight and Waist circumference.

3.3.3.1 HEIGHT MEASUREMENT:

The SECA body meter (206 seca Vogel and Halke GmbH and Co. Sonke Vogel Geschalfsfuhrer) was use for this measurement. The techniques for measurement of height are as follows:

1. The instrument is assembled on a vertical solid surface.
2. The respondent is asked to remove shoes, socks, slippers and headgear.
3. The respondent is asked to stand on the board, facing the interviewer, putting their feet together, heals against the back of the board, knees straight.
4. The respondent is asked to look straight ahead and not to look up.
5. The interviewer moves the measuring stick down and place on top of the head.
6. The height is read in Cm to exact point and recorded.

3.3.3.2   Weight Measurement:

A TANITA digital scale (2003 Tanita Corperation of America, Inco. Arlington Heights IL 60005) was used for weight measurement. The procedure for weight measurement was as follows:

1. The scale is put on a firm flat surface. Not on carpet or a sloping surface.
2. The instrument reading is set.
3. The respondent is asked to remove footwear and socks, step on the scale with the feet on each of the footpads, facing forward, arms on the side and standing still until the reading is taken.
4. The weight is read in Kg and recorded in the questionnaire.

3.3.3.3   Waist Circumference Measurement:

The tension measuring tape graduated to 1 mm was used for this measurement. A private area is chosen for this measurement. The measurement is taken without clothing using following technique:

1. The inferior margin of the last rib and the superior border of the iliac crest in the mid axillary plane are located and marked with a pen.
2. The mid point between the 2 is found with a tape measure and the point marked.
3. The tension tape is applied over the marked point making sure that the tape is horizontal across the back.
4. The respondent is asked to stand with their feet together, with arms placed at the sides with palms of the hand facing inwards and to breathe out.
5. The measurement to the nearest 0.1 cm is taken at the point of breathing out. The measurement is taken only once and recorded.

3.3.3.4   Blood pressure measurement:

The measurements were taken using the OMRON digital sphygmomanometer (OMRON M7 *Duo* 773 omron Healthcare Europe B.V. Kruisweg 577, 2132 NA Hoofddorp).

Before taking the measurement:
1. The respondent was advised to sit quietly and rest for 5 minutes with the legs uncrossed.
2. The right arm was used and free of clothing.
3. The right arm was placed on the table with the palm facing upwards.
4. The appropriate cuff size was selected.
5. The artery position mark (ART) was aligned with the brachial artery.
6. The cuff was wrapped snuggly and fastened securely. The lower edge kept 1.2 – 2.5 cm above the inner side of the elbow joint.
7. The cuff was kept at the same level as the heart during measurement.

Taking measurement:
1. Push START button.
2. The displayed reading of the systolic and diastolic blood pressure are taken and recorded.
3. The second reading is taken after the first.
4. If the difference between the 1st and 2nd readings is 10 mmHg or more, then there is need for 3rd reading.
5. The readings are recorded in the questionnaire.

3.4   DATA **MANAGEMENT** AND ANALYSIS

Questionnaires collected from the field were reviewed by team leaders assigned to each team before submitting them to the headquarters for data entry.

Double entry of the questionnaires was performed using EPI-INFO 2000 software and EpiData soft ware developed by Menzes center for validation.

After the data entry, the data cleaning was conducted.

New variables were defined by adopting the standard Steps variables (STEPS Data Management Manual, Draft version v1.5, October 2003).

Data analysis was conducted using EPI_INFO 2002 and SPSS softwares.

3.5 QUALITY ASSURANCE

To ensure quality of data collection, the interviewers and the supervisors were carefully selected.

The supervisors were senior staff from the WHO, Orotta School of medicine and the ministry of health. The interviewers were lead by public health students from Asmara University who had previous research experience and included final year nursing students as well as medical students from Orotta School of medicine.

The questionnaire was translated into the local Tigrinya language and pre-tested.

Intensive training was given to the data collectors, which included practical sessions and questionnaire and equipment testing.

A guideline was prepared and given to the teams for easy reference. Also in order to minimize error, digital equipment was used for measuring weight and blood pressure.

In order to minimize data entry errors, double data entry was carried out and checks were instituted into the data bases.

3.6 ETHICAL CLEARANCE AND CONFIDENTIALITY

The survey was cleared by the Ministry of health and had the full support of the Orotta School of medicine.

A letter from the ministry of health signed by the Director general detailing the survey objectives and seeking co-operation and support from all stakeholders was carried by each survey team.

In the field, clearance was always obtained from the zonal and village administration.

Verbal informed consent was obtained from all respondent before administering the questionnaire or taking measurements.

3.7 MAJOR PROBLEMS ENCOUNTERED DURING THE SURVEY

The major constraints encountered during the survey included:

1. Absence of selected candidates from the houses because of farming season making the interviewers go back many times before getting response.

2. The data was so heavy for analysis to be run in Epi Info. We had to export it to SPSS for better analysis

4.0   RESULTS

4.1   RESPONSE RATE:

At the onset of the interview, 2460 respondents were targeted in 123 clusters of 20 individuals per cluster. Eventually, 2352 individuals responded in 113 clusters responded giving a response rate of 95.6%. The response rate per Zoba as presented in Table 4.1, ranges from 71 to 100%, with only Zoba Northern red sea presenting a response rate of below 90%. This is because, the supervisor of one of the teams sent to that Zoba dropped 5 clusters in response to a mistake in population estimation.

Table 4.1   Response Rate by Zoba:

Zoba	Target		Response	
	No. of Clusters	No. of Subjects	No. of Respondents	Percentage
Anseba	20	400	400	100
Debub	31	620	620	100
Gash-Barka	24	480	98.8	98.8
Maekel	24	480	480	100
NRS	18	360	257	71
SRS	6	120	120	100
Total	**123**	**2460**	**2352**	**95.6**

4.2   MISSING VARIABLES:

The missing variables are mostly found in the section on alcohol use where quantities of alcohol taken and the period of use were missing in most of the questionnaires. However, certain clusters as shown in table 4.2, missed

important variables like sex, age and physical measurement. In fact, one interviewer in Northern red sea consistently took only 1 BP reading.

Table 4.2   Missing Important Variables:

Missing Variable	No. of Clusters	List of clusters
Age	1	D26
Sex	6	G03, G02, G06 (3), D24
Both 2nd and 3rd BP	29	G11, M11, M13, N09 (7), N10 (8), N11 (9), N12, D05.
Height	29	A05, A13, D01 (2), D06 (3), D14 (2), D15, D17(2), D19, D20, D27, D28, M13 (2), M15 (2), M17, N01, N03, N06, N09, N11
Weight	11	D06, D14, D20, D27, G11, G17, M01, M15 (2), M17, M19.
Waist Circumference	40	D02, D06, D07, D15, D17(2), D25, D28, D30, G04, G10, G12 (2) G13, G17, G19, G20, G21 (2) G22 , G24 (4), G25, M05, M11, M17 (2), M18 N03, N05, N07, N08, N13 (2),

4.3   SOCIO-DEMOGRAPHIC CHARACTERISTICS:

4.3.1 AGE AND SEX DISTRIBUTION:

The subjects were all within the age range of 15 to 64. The age group and sex distribution are presented in table 4.4. Only 2 subjects were excluded from the age-sex analysis based on age alone, one with age unknown the other with age missing. The rest were excluded based on missing sex.

As can be seen from Table 4.4, the subjects were uniformly distributed among the groups and sex for all Zobas.

Fig 1

Distribution of respondents by Zoba

	Ansaba	Debub	Gash Barka	Maekel	NRS	SRS
Respondents	400	620	475	480	256	120
4.3.2 DISTRIBUTION OF RESPONDENTS BY SOURCE OF INCOME:

Majority of respondents mentioned either formal employment or Farm Product as the source of income for the family with 37.7% and 32.4% respectively (P value < 0.05%). The distribution of the respondents by source of income and by Zoba is presented in Table 4.3. Formal employment as source of income highest in Zoba Maekel (66.9 %). In Zoba Debub, half of respondents rely on Farm produce as source of household income. Farm produce is also the main source of income in Zoba Anseba and Gash-Barka. More people live on Aid in Northern red sea and Southern red sea than other Zoba (12.8 and 7.5% respectively).

Table 4.3   Distribution of Source of Income by Zoba:

Zoba		Source of Income (%)								
		Aid	Business	Daily Labor	Farm Product	Formal Employ.	National Service	Other	Remittance	total
Anseba	N = 400	2.0	3.5	4.3	41.0	32.8	2.5	10.0	4.0	100

4.3.3 Religious Persuasion:

The religious belief of the respondents by Zoba is presented in Table 4.6 The highest group was Orthodox Christians with 55.7 %, Followed by Muslims 36.4%. The Catholic and Protestant Christians constitute 6.6 and 1% respectively. This proportion varies from Zoba to Zoba. This result is statistically significant (P value < 0.05 at 95% confidence interval).

4.4   NCD RISK FACTORS (STEP 1)

4.4.1 Smoking:

The prevalence of smoking by Zoba is presented in Table 4.11. The result is significant at 95% CI. Overall 8% of the sampled population smokes. The daily smokers constituted 7% of the sampled population, while 1% was non-daily smokers. The prevalence of daily smoking was highest in Zoba Gash-Barka with 10.2%, followed by Zoba Maekel with 7.7%. The lowest prevalence was in Zoba Debub with 5.2%.

The ex-daily smokers constituted 3.6%. This percentage in Zoba Anseba, Northern red sea and Southern red sea with more than 6 % prevalence of ex-smokers.

The distribution of prevalence of smoking by Age group and sex as shown in Table 4.12 reveal that the prevalence of smoking was significantly higher among males than females. In fact, none of the females reported being an ex-smoker and the prevalence of current daily smokers among females was less than 1% for all age groups.

The modal age group for current daily smoking prevalence among males was 35 -44 years with prevalence of up to 21.6%.

4.4.2. PREVALENCE OF SMOKELESS TOBACCO USE:

The prevalence of smokeless tobacco use was less than that of smoked tobacco. As can be seen from table 4.17, the National prevalence of current use of smokeless tobacco was 2.9%. The prevalence ranges from 0.4% in Zoba Maekel to 6.6% in Northern red sea. The prevalence is low in the High Lands and seem to be reducing in most Zobas when the current daily users are compared to ex-daily users.

Most users are males of the older age groups of 45 years and above (Table 4.18). Most users use either chewing tobacco – 53.8% or snuff by mouth 35.0% (Table 5.4.2.3). The quantities of chewing Tobacco and snuff by mouth used are presented in Tables 4.19 and 4.20 respectively

4.4.3 Alcohol

In this survey "Drink Ever" is defined as a person who has ever consumed alcohol, while "Drinker" is defined as a person who consumed alcohol in the last 12 months. The prevalence of "drinker" and "drink ever" are presented in Table 4.21. The "drink ever" prevalence was 42.9% and that of "Drinker" was 39.6%. The drinker prevalence was lowest in Southern red sea, 8.4% and highest in Debub, 62.5%.

The prevalence of Drinker was higher among males than females and it rises with age group until age group 55 – 64 when the prevalence drops slightly (Table 4.22).

The quantity of standard drinks consumed per drinking day in the last 12 months by Zoba is presented in Table 4.27. The quantities are paradoxically higher in Zobas with low drinker prevalence.

High daily alcohol consumption is defined as daily alcohol of greater than 4 drinks and is presented in Table 4.28. The prevalence was highest in Anseba with 14%, followed by Gash-Barka with 8.9%.

Table 4.27 Percentage distribution of respondents by number of standard drinks consumed per day in Last 12 Months per Zoba

4.4.4 Diet

Low fruit consumption is defined as consumption of less than 2 servings of fruit per day. The prevalence of low fruit consumption by Zoba as seen in Table 4.29 shows that, the prevalence was quite high, 84.7%. It was highest in Debub and lowest in Gash Barka. There is no significant difference between males and females and between age groups (Table 4.30). The prevalence of low fruit consumption was slightly higher among those who did not go to school but no difference between grades of education for those who went to school (Table 4.31). The prevalence was highest among those who report their employment as Farming and lowest among civil servants (Table 4.32)

Low Vegetable consumption is defined as consumption of less than 2 servings of vegetable per day. The prevalence of low vegetable consumption by Zoba can be seen in Table 4.33 The prevalence was lower than low fruit; 50.6%. It was highest in Southern red Sea (71.1%) and lowest in Gash Barka (44.2%). There was no significant difference between males and females and between age groups (Table 4.34). The prevalence of low vegetable consumption decreases with increasing educational level (Table 4.35). The prevalence was highest among those who report their employment as Farming and lowest among local merchants (Table 4.36).

4.4.5 Physical Activity

Inactivity is defined as work mostly sitting; transport not walking or using a bicycle; rest and leisure involving mostly sitting. The prevalence of inactivity by Zoba is presented in Table 4.37. The National prevalence of inactivity was 10.1%. It was highest in Northern Red sea with 21% and lowest in Debub with 7.0%. The prevalence was Zero in Southern Red Sea.

Table 4.37   Prevalence of Inactivity by Zoba

NRS	254	78.3	21.7	
SRS	120	100.0	0.0	
TOTAL	2338	89.9	10.1	

Age and Sex distribution of Inactivity shows that there was no difference between the males and females or between age groups (Table 4.38). The prevalence by educational level as seen in Table 4.39 reveals that for those who went to school, the prevalence of inactivity increases with increasing education. For the types of employment, inactivity was highest among local merchants (14.2%) and lowest among the National service – 5.2% (Table 4.40). The rural dwellers have a slightly higher level of inactivity than urban dwellers which however was statistically not significant, p-value = 0.093 (Table 4.41)

The percentage distribution of the respondents with regards to the level of physical activity during work shows that 60.6% were inactive at work, 18.8 did moderate work related physical activity, while 20% did vigorous activity. The level of work related inactivity was highest in Zoba Maekel (74%) and lowest in Southern Red sea (39%) – Table 4.42.

For transport related inactivity (Table 4.43), the national prevalence was 15% with highest prevalence 38.8% in the NRS Zoba. Thus, 75% of the total respondents either cycle or trek to work.

The Leisure related inactivity prevalence was 91.5%. This was highest in Northern red sea (96%) and lowest in Debub (86%) – Table 4.44

4.5 NCD RISK FACTORS (STEP 2 PHYSICAL MEASUREMENTS)

The mean, median and standard deviations of the physical measurements are presented in Table 4.45.

The mean height was 162.29 cm with a standard deviation of 11.37.

The mean weight was 54 with a standard deviation of 11.31.

The mean BMI was 21.01 with SD of 4.9.

The mean SBP was 119.15 mmHg with SD of 18.4 and

The mean DBP was 77.12 with SD of 13.7.

Table 4.45   Statistical measures for physical measurements:

4.5.1 PREVALENCE OF OBESITY (HIGH BODY MASS INDEX)

Obesity (High Body mass index) is defined as body mass index of 30 kg/m² and above. The prevalence of High Body mass index as shown in Table 4.46 was 3.3%.

If we add those who are overweight (those who are at risk of becoming obese), the prevalence gets up to 13.7 %, which is not small at all. This prevalence was

highest in Southern Red sea and Zoba Maekel and lowest in Zoba Anseba and Gash-Barka (table 4.46a).

The high body mass index prevalence was higher in Females than in Male and was likewise higher in middle age groups and the elderly (Table 4.47)

Table 4.46a Percentage Distribution of respondents by BMI category and age group and sex (P 0.000)

4.5.2   WAIST CIRCUMFERENCE:

Table 4.48 shows that most of the respondents had a waist circumference that lies between 61 and 80 cm (63.3%). Thirty one percent had a waist circumference above 80 cm. High waist circumference was highest in Zoba Maekel and Southern red sea. This is similar to the prevalence of High BMI. But unlike High BMI, the males tend to have higher values of Waist circumference than female (Table 4.49)

About 25-30% of women have a WC > 80 cm (Normal value for female) and just about 2% of the men have a WC >100 cm (normal value = 94 cm for men

Table 4.48   Percentage distribution of respondents by Waist Circumference and by Zoba (P 0.000)

4.5.3 PREVALENCE OF HIGH BLOOD PRESSURE

High Blood pressure is defined as Systolic Blood pressure of 140 mmHg and above and or Diastolic Blood pressure of 90 mmHg and above. The prevalence of high blood pressure using this definition was 15.9% - Table 4.50 The prevalence was highest in Zoba Maekel with 19.2% and lowest in Southern red sea with 8.3%.

The prevalence of high blood pressure with the cut off point of systolic blood pressure at 160 mmHg and above or diastolic of 95 mmHg and above is 6.6%. Zoba Maekel still retained the highest prevalence at this cut off point – Table 4.51

Table 4.50   Percentage distribution of respondents by level of Blood Pressure and by Zoba (high BP cut off = SBP >=140 mmHg and or DBP >= 90 mmHg). (P 0.004)

TOTAL	2348	93.4	6.6

The prevalence of High blood pressure is higher among males up to age group 35 – 44 years, there after it is reversed and became more prevalent among the females. The prevalence rises with age (Table 4.52). The prevalence of High blood pressure drops with educational level from those who did not attend school up secondary grades. The prevalence then rises at Higher grades after secondary grades – (Table 4.53). The prevalence among different employment categories (Table 4.54) reveals that it is highest among the local merchants and un-employed (>24%) and lowest among the Students (7.1%). Table 4.55 presents the distribution of the prevalence of high blood pressure by source of income. Those respondents whose major source of household income is Aid, Business or Remittance have higher prevalence (> 20%). Those who reported source of household income as Daily Labour, Farm products or National service have lower prevalence (< 14%). The prevalence is also higher among those with Per capita income earning > 18,000 Nakfa per annum Table 4.56. The difference between Urban and Rural settings in terms of prevalence of high blood pressure was not statistically significant (Table 5.57).

4.5.4 Blood Pressure Check:

As can be seen from Table 4.58, more than half of the respondents with high blood pressure had not had their blood pressure checked for more than a year and 33% for more than 5 years.

Of those with high blood pressure, 82.9% were not aware of this situation prior to the survey (Table 4.59) and only 11.9% reported receiving treatment (Table 4.60). Among the respondents with high blood pressure, 0.8% had consulted traditional healer for treatment – P value of 0.68 (Table 5.61) and only 1.7% are on herbal treatment (Table 4.62). Family history of high blood pressure among those with high blood pressure as shown in Table 4.63 is not significantly

different from those with normal blood pressure at 17.9% and 16.4% respectively. It is the same scenario with family history of diabetes (Table 4.65). However, there is a significant difference between the 2 groups in the diagnosis of diabetes. Those with high blood pressure have higher prevalence of diabetes diagnosis (5.4%) than those with normal blood pressure (1.7%) – Table 4.64.

4.5.5 High Blood Pressure and Risk Factors:

High blood pressure is significantly higher among those with waist circumference reading higher than 80 cm – Table 4.67. It is also higher in those with high body mass index – Table 4.68. The high blood pressure is also higher among drinker than non-drinker – Table 4.69. High blood pressure is not significantly related to daily smoking or daily use of smokeless tobacco. However it is significantly related to the duration of smoking (Tables 4.70 – 4.72). The prevalence is also higher among the sedentary than active especially among those who are physically inactive at work (Tables 4.73 and 4.74).

Table 4.67   Percentage distribution of respondents by Blood Pressure Type and by Waist Circumference

5.0 DISCUSSIONS

Hospital and outpatient mortality data due to non-communicable diseases in the country has shown a steady rise in incident trends over the years. This mortality rate for hypertensives related diseases move from 5% in the year 2003 to 7% in the year 2004. This global rising epidemic of non-communicable diseases that has also hit Eritrea is a call for surveillance, prevention and control. This baseline survey which is an entry point to a national intervention programme has brought out quite interesting revelations that corroborate the hospital observations vis à vis NCDs.

The survey was carried out within scientific norms as prescribed by the WHO STEPwise approach. The sample size was adequate and representative of sex and age group. WHO recommends at least 200 subjects per sex per 10-year age group. This survey had five age groups from 15 to 64 years and would have been expected to have a sample size of at least 2000 subjects (1000 men and 1000 women). With a total of 2352 subjects examined (1176 per sex), this figure is well above the cut off of the recommended sample size.

Regarding the response rate, WHO recommends a minimum rate of 75% for NCDs. This survey had a very comfortable response rate of 95.6%.

With more than 60% of the population not having had any formal education or attained only the primary grade and coupled with the fact that most of them were peasant farmers by profession, this certainly had an impact on their health seeking behaviors and awareness on NCDs. This can be observed in the fact that up to 80% of those who were diagnosed for High Blood Pressure were done so for the first time. In addition, more than 40% of the population had not had their BP checked for the past 5 years.

Regarding the risk factors, and considering tobacco smoking, it will be realized that the fact that men are 15 times more than women as current daily smokers is actually culturally linked as is the case in most African countries. It has to be noted that in most western countries, the sex difference is not significant. This implies that a national non-tobacco campaign will succeed better if the men are

targeted. In the same line, given that the prevalence is highest in the Gash Barka Zoba, a more focused intervention in this zone as a pilot sentinel site would definitely yield more fruits.

Alcohol consumption has been known to be a social ill in most communities in the world with prevalence rates getting close to 100 % in the adult population in some settings. The 40% prevalence rate is quite high given the fact that alcohol consumption is a major risk factor for most cardiovascular diseases. Even though the prevalence of alcohol consumption is highest among the orthodox Christians, which explains why its prevalence is also highest in the Debub and Maekel Zoba, it must be noted that it is increasingly becoming prevalent in those of Islamic religion who are normally supposed to be alcohol free as seen in the SRS Zoba.

Fruit and vegetable consumption is generally not in the habit of the population even though they are mainly farmers by profession. The prevalence values of 85% and 51% respectively are extremely high. As indicated earlier, educational level and level of income go with increase rates of vegetable and fruit consumption. This means that there is probably a problem of awareness.

The fact that 90% of the general population is physically active is impacted on the low prevalence of obesity (3.3%) and small mean weight value (55.23kg). However, obesity and overweight put together gives a prevalence rate of 13.7%. If nothing is done to check the 10% overweight prevalence, those of this class will gradually cross over to, and swell up the class of those who are obese in the years ahead.

 Even if the general obesity prevalence is low, the abdominal obesity is 25% to 30% in women where the waist circumference is >80cm. It has to be noted that in terms of health hazards, abdominal obesity is more dangerous than uniformly distributed fat.

A 15 % prevalence rate of high blood pressure in the adult population is significantly high. The steady rise in BP with age on the one hand and the sex cross over at 45 to 50 years of age on the other is quite characteristic. What is also outstandingly characteristic is the fact that it is more prevalent in those who

are either overweight or obese (> 55%) and the economically more empowered (probably due to overweight) or the unemployed (stress).

Just 11% of the hypertensives patients are on treatment, which means that close to 90% are not treated. It is absolutely necessary to set up a system that will take care of them.

A prevalence of 2.2 % of known cases of diabetes in the population is quite a big figure. If about 80 % go undiagnosed, as is the case with hypertension, then the prevalence should be well over 11%, which is quite alarming. This can already be portrayed in the hypertensives where the prevalence is 5.4% (as diagnosed in the health facilities).

6.0   CONCLUSIONS

CONCLUSION

•This study has provides robust new knowledge on NCDs and their risk factors in Eritrea

• The prevalences have reached critical points

• Most of the cases go undiagnosed and management by health professional is poor

• These conditions will add an additional burden to an already overwhelmed health system

• Something must be done now.!!

7.0 RECOMMENDATIONS

1. That a national NCD programme should set up as soon as possible, an intervention package consisting of surveillance, prevention and control strategies to contain this rising epidemic.

   a. Surveillance:

      i. Disseminate baseline survey results

      ii. Set up a routine health facility based morbidity and mortality data collection and analysis system

      iii. Set up a community based risk factor surveillance system

      iv. Integrate NCDs in the already well functioning IDRS system

   b. Prevention:

      i. Draw up a national media plan for NCDs

      ii. Produce awareness packages (posters, stickers, fliers , health talks etc.) that cut across socio –cultural groups

      iii. Draw up and enact Health protection policies on tobacco and alcohol

   c. Control:

      i. Produce NCD management guideline and algorithms for the different major NCDs.

      ii. Build capacity of health providers at all levels on the use of the guidelines

      iii. Provide basic equipment to the different health facilities depending on the technical level

      iv. Set up a national essential drug procurement system for NCDs

      v. Set up a good referral and counter referral system for complicated cases of NCDs.

2. That step 3 of STEPS be carried out to determine the real situation of diabetes and dyslipidemias in the community for better management.

MINISTRY OF HEALTH ERITREA
NCDs RISK FACTORS SURVEY 2004 – TRAINING OF INTERVIEW TEAMS

AGENDA

DAY 1: Saturday 4th September, 2004.

TIME	TOPIC	FACILITATOR
8.30 – 8.50 am	Survey Objectives and Expectations	Dr. Goitom Mebrahtu
8.50 – 9.10 am	STEPS	Dr. Yohannes Ghebrat
9.10 – 9.40 am	Interview approach, techniques and sampling	Dr. A. Usman
9.40 – 10.10 am	Tea Break	All
10.10 – 10.30 am	General overview of the questionnaire	Prof. Peter Nyarang'o
10.30 – 10.50 am	Tobacco Use	Mr. Asgedom
10.50 - 11.10 am	Alcohol Consumption	Prof. Jacob Mufunda
10.10 – 11.30 am	Diet	Dr. Musie E-Mikail
11.30 – 11.50 am	Physical activity	Dr. A. Usman
11.50– 12.10 pm	Hypertension and diabetes	Dr. Goitom Hagos
12.10 – 12.40 pm	Introduction to physical measurements	Prof. Mufunda/ Dr. Goitom Hagos
12.40 – 2.00 pm	Lunch Break	All
2.00 – 4.00 pm	Practice on questionnaire and physical measurements	All.

DAY 2: Sunday 5th September, 2004.

TIME	TOPIC	FACILITATOR
8.30 – 9.00 am	Recap of day 1	Dr. A. Usman
9.00 – 9.30 am	Feedback on practicals	Prof. Jacob Mufunda

9.30 – 10.00 am	Tea break	All
10.00 – 11.30 am	Practicals continued	Prof. Peter Nyarang'o
11.30 – 12.00 am	Wrap up and postings	Dr. Goitom Mebrahtu

NCDs RISK FACTORS SURVEY
TEAM COMPOSITION:

TEAM 01
ZOBA MAEKEL
1. DR. GOITOM HAGOS
2. ABRAHAM K. ISAK
3. TADESSE TEWOLDE
4. ORKABAHANS KAHSAY
5. JABIR M.I. SALEH
6. KIBROM ASMELASH
7. EDEN HAILE MOSAZGI

TEAM 02
ZOBA MAEKEL
1. DR. GOITOM MEBRAHTU
2. DR. TESFAZION
3. ESMAIL O. ALI
4. AMANUEL D. G/MARRIAM
5. MICAL ABRAHA TUCCU
6. MERON TECLA BERHA
7. EYOB F. G/BERHAN
TEAM 03
ZOBA DEBUB
1. MR. ASGEDOM
2. YORDANOS M. TEDLA
3. SAMUEL H. DRAR
4. ASMEROM T. SENGAL
5. MOHAMMED O. ABDELLAH
6. BISIRAT T. KELETA
7. AMANUEL H. ZERU
8. AINOM O TEDLA

TEAM 04
ZOBA DEBUB
1. DR. MUSIE E-MIKAIL

2. NEGUSSI R. G/MEDHIN
3. HANS H. MENGHISTAB
4. DANIEL T. G/SELASSIE
5. ABRAHAM H.K/MARIAM
6. KIFLOM Y. GEBREAB
7. TIGISTI H. G/MESKEL

TEAM 05
ZOBA NORTHERN RED SEA
1. PROF. J. MUFUNDA
2. TECKLE WERDE
3. AMANUEL A. HAILE
4. YODIT Z. T/MARIAM
5. TESFAHIWET G/MARIAM
6. BAHABELOM M GHEBRAI

TEAM O6
ZOBA NORTHERN RED SEA
1. MR. MUKTAR IBRAHIM
2. HAILAB MESFIN
3. ALEMTSEHAY NEGASSI
4. TSEGHA GOITOM
5. WARDA HASSEN
6. AMAN HADGU

TEAM 07
ZOBA ANSEBA
1. MR. AMANUEL YOHANNES
2. ELIAS TEAGAS
3. ASKALE G/KRISTOS
4. MERKEB TEWOLDE
5. RITA T/BERHAN
6. BINIAM GHIRMAY

TEAM 08
ZOBA ANSEBA
1. DR. YOHANNES GHEBRAT
2. SELAMAWIT ANDEBERHAN
3. ESEYAS S TSEHAYE
4. AMNUEL B MESFIN
5. NASSER ADEM SALE
6. MUSIE Y WOLDU

TEAM 09

ZOBA GASH-BARKA
1. DR. ESTIFANOS PAULOS
2. ZEKARIAS ANDEMARIAM
3. ASMERET BYENE
4. MARTA DESBELE
5. DANIEL OGBAGABR
6. MULUGHETA G/KRISTOS

TEAM 10
ZOBA GASH-BARKA
1. PROF. PETER NYARANG'O
2. MULLA TESFAMIKAIL
3. LAINE OKBAZGI
4. FIYORI T/MARIAM
5. LUWAM T/GABIR
6. WEINI TEKLU
7. FESEHA HADISH

TEAM 11
ZOBA SOUTHERN RED SEA
1. DR. A. USMAN
2. TEWOLDE KIDANE
3. HANNAN M. OSMAN
4. HIRITY KIFLAY
5. FISHALE MELONEN
6. TESFALEM TEKLAI

MINISTRY OF HEALTH ERITREA
NCDs RISK FACTORS SURVEY 2004 – TRAINING OF INTERVIEW TEAMS

AGENDA

DAY 1: Saturday 4th September, 2004.

TIME	TOPIC	FACILITATOR
8.30 – 8.50 am	Survey Objectives and Expectations	Dr. Goitom Mebrahtu
8.50 – 9.10 am	STEPS	Dr. Yohannes Ghebrat
9.10 – 9.40 am	Interview approach, techniques and sampling	Dr. A. Usman
9.40 – 10.10 am	Tea Break	All
10.10 – 10.30 am	General overview of the questionnaire	Prof. Peter Nyarang'o
10.30 – 10.50 am	Tobacco Use	Mr. Asgedom
10.50 - 11.10 am	Alcohol Consumption	Prof. Jacob Mufunda
10.10 – 11.30 am	Diet	Dr. Musie E-Mikail
11.30 – 11.50 am	Physical activity	Dr. A. Usman
11.50 – 12.10 pm	Hypertension and diabetes	Dr. Goitom Hagos
12.10 – 12.40 pm	Introduction to physical measurements	Prof. Mufunda/ Dr. Goitom Hagos
12.40 – 2.00 pm	Lunch Break	All
2.00 – 4.00 pm	Practice on questionnaire and physical measurements	All.

DAY 2: Sunday 5th September, 2004.

TIME	TOPIC	FACILITATOR
8.30 – 9.00 am	Recap of day 1	Dr. A. Usman
9.00 – 9.30 am	Feedback on practicals	Prof. Jacob Mufunda
9.30 – 10.00 am	Tea break	All
10.00 – 11.30 am	Practicals continued	Prof. Peter Nyarang'o

11.30 – 12.00 am	Wrap up and postings	Dr. Goitom Mebrahtu
